ambito collinare periadriatico.

climatologica e geomorfologica per affrontare lo studio di un dissesto in

2) Il candidato descriva gli elementi di analisi preliminare Geografica,

strutturale per la verifica di stabilità di un ammasso roccioso fratturato.

1) Descrivere come impostare una campagna di indagini di tipo geologico

TEMI 1<sup>a</sup> PROVA SCRITTA - 23/11/2016

ESAME DI ABILITAZIONE ALLA PROFESSIONE DI GEOLOGO - SEZ. B junior

ALLEGATO 4

## **Esami abilitazione geologo sezione B**

### **II prova scritta**

#### **Tema 1**

Si rediga un piano di indagini, con prove in situ e di laboratorio, nell'ambito del progetto per la realizzazione di un edificio pubblico, adibito a scuola, localizzato nella fascia collinare periadriatica. Si motivi la scelta delle varie indagini, evidenziando i vantaggi e le criticità di ciascuna delle scelte effettuate.

#### **Tema 2**

Il candidato descriva la metodologia, i dati e le informazioni necessarie per la redazione di una Cartografia di suscettibilità all'inquinamento di un acquifero alluvionale monostrato, in un contesto di piana alluvionale di un fiume adriatico, ove sorgano complessi industriali e commerciali.

#### **Tema 3**

In allegato sono riportati i tabulati relativi ad una prova penetrometrica statica con punta meccanica.

Il candidato:

- descriva il contenuto e le modalità di acquisizione/elaborazione delle diverse colonne contenute nei tabulati della prova CPT;
- descriva i parametri geomecanici ricavabili dalla prova CPT;
- proceda alla discretizzazione e parametrizzazione (in termini di parametri geotecnici nominali) del profilo di sottosuolo indagato dalla CPT.

# LEGENDA

## QUATERNARY CONTINENTAL DEPOSITS

**Eluvio-coluvial deposits**  
Silty-clay deposits, colluvial origin with sand fraction and with elements depending on the nature of the feeding basin. *Pleistocene - Holocene*

**Slope deposits**  
Scree and talus deposits with variable grain size, well sorted or heterometric, unconsolidated or poorly cemented. The clasts are very angular to little or moderately rounded. *Pleistocene - Holocene*

**Landslide deposits**  
Chaotic deposits with variable grain size, emplaced due to gravitational processes. *Holocene*

**Alluvial deposits**  
a) alluvial deposits: mainly calcareous gravels, occurring along river beds.  
b) alluvial fans: polygenic conglomerates, sands and silty-clay layers massive or thinly laminated. *Pleistocene - Holocene*

**Fluvi-lacustrine deposits**  
Fine grained sediments and peat levels, mixed with coarser elements, deposited in lacustrine, fluvial-lacustrine and marsh swamp environments. *Middle / Upper Pleistocene - Holocene*

**Moraine deposits**  
Chaotic deposits composed of heterometric clasts, up to the block size, with a silty matrix, locally cemented. *Pleistocene? - Holocene*

**Travertines**  
Travertines and calcareous silt of fluvial and lacustrine environment. *Pleistocene - Holocene*

## MARINE SUCCESSION

### LAGA BASIN

**Laga Formation**  
Turbiditic sandstones which consist of three members: pre-evaporitic, evaporitic and post-evaporitic members. The first (LAG<sub>1</sub>) is formed by some lithofacies associations: arenaceous (prevailing), arenaceous-pelitic and pelitic-arenaceous, defined by the sandstone/pelite ratio, which alternate in a vertical direction. The thickness is about 800 m. The evaporitic member (LAG<sub>2</sub>) consists essentially of an arenaceous lithofacies that includes a level of black arenic bituminous marls and the typical "gessarenico key-bed" (G). The thickness is about 500 m. In the northernmost sector this member is replaced by the bituminous clays and marls of the Gessoso-solfiera Formation (GES). The post-evaporitic (LAG<sub>3</sub>) member is prevalently formed by a pelitic-arenaceous lithofacies in which numerous arenaceous-pelitic and arenaceous levels are inserted. In the upper part the "volcanoclastic key-bed" (V) is present. The outcropping thickness is 900 m. *Messinian*

**Marna con Cerroga - Schlier**  
The Marna con Cerroga are constituted by light grey marls, calcareous marls and clayey marls with medium to thick bedded calcareous turbidites. A severe bioturbation is present. The uppermost part (Marna a Pteropodi) consists of grey-green marls and clayey marls, bituminous and laminated in the upper part. The thickness is 100-300 m. In the northernmost sector the Marna con Cerroga Unit is replaced by the Schlier. *Burdigalian p.p. - Early Messinian*

### CAMERINO BASIN

**Camerino Formation**  
Arenaceous turbidites, formed by three lithofacies: arenaceous, arenaceous-pelitic and pelitic-arenaceous lithofacies, which are defined by the sandstone/pelite ratio. The lithofacies are spatially associated in different ways. The thickness is about 500 m. *Tortonian p.p. - Messinian p.p.*

**Schlier**  
Grey marls and clayey-siltose marls, white calcareous marls and calcarenous levels. The thickness varies from 60 to 200 m. *Burdigalian p.p. - Tortonian p.p.*

**Biscaro**  
Dark grey marly and siliceous limestones, limestones with black cherts nodules, in medium to thick beds, alternated with grey calcareous marls and clayey marls. The lower part contains thin intercalations of altered carbonaceous volcanoclastic. Frequent bioturbations are also present. The thickness varies from 50-60 to 100-150 m. *Aquitanian p.p. - Burdigalian p.p.*

**Scaglia cinerea**  
Green-grey to cinder-grey calcareous marls, marls, and clayey marls, in medium-thin beds. Subordinately there are marly limestone levels especially in the lower part. Grey calcarenites, rich in Nummulites, in 10-60 cm thick levels, are also present. The unit is 200 m thick. *Bartonian p.p. - Aquitanian p.p.*

**Scaglia variegata**  
Red, grey and green limestones and marly limestones, in thin-medium beds, alternated with grey and red marls and calcarenous marls. The maximum thickness is about 50 m. *Lutetian p.p. - Bartonian p.p.*

**Scaglia rossa**  
Pink, dark, red, rarely white marly limestones and limestones, stratified in medium beds, with very thin pelitic levels and red or pink chert in nodules and ribbon missing in the middle part. The latter contains thick marly levels. Thick grey or white calcarenous levels are also present. The thickness is 250-450 m. *Lower Turonian p.p. - Lutetian p.p.*

**Scaglia blanca**  
White limestones and marly limestones, in medium beds, with chert beds and ribbons, black or brown in the upper part, pink in the lower one. In the uppermost part, the "Lello Bonarelli", made up of black arenic bituminous shales, is present, with a maximum thickness of 1.5 m. The usual thickness of the unit is about 50-80 m. *Upper Albian p.p. - Lower Turonian p.p.*

**Marna a Fucoldi**  
Grey, green and red marls and shaly marls, marly limestone, with abundant clay levels, frequently bituminous ("black shales"). The marls and the shaly marls prevail in the lower part, the marly limestone in the upper one, where the green chert is also present. Calcarenites and calcirudites are frequent. The thickness varies from 50 to 80 m. *Lower Aptian p.p. - Upper Albian p.p.*

**Maiolica**  
White and ivory calcilutites, in thin-medium beds, containing grey chert nodules and lenses, black in the upper part, white or grey in the lower one. The thickness is variable ranging from 150 to 450 m. *Upper Tithonian - Lower Aptian p.p.*

## COMPLETE JURASSIC SUCCESSION

**Calcareo diaspriigni**  
The lower portion of the Calcareo diaspriigni is formed by red, green and grey, finely to very finely bedded, siliceous calcilutites, alternating with green, red or grey cherts and some marly levels. Locally clastic and bioclastic limestones, in medium to very thick beds, are present ("Membro selciato"). The upper part ("Calcareo a Saccocoma e Apiti") is characterized by grey, green, sometimes red, cherty limestone, in medium-thin beds, frequently with apitchi. The maximum thickness is about 150 m. *Upper Bajocien - Lower Tithonian*

**Calcare a Posidonia**  
Whitish or brown limestones and marly limestones, sometimes nodular, stratified in medium beds, with abundant Posidonia filaments and cherts increasing upward. Clastic and bioclastic limestones, stratified in medium - to very thick beds, are present. The maximum thickness is about 200 m. *Upper Toarcian p.p. - Lower Bajocien*

**Rosso ammonito**  
Dark red, pink, sometimes grey-green nodular limestones and marly limestones alternating with red marls and shaly marls. The whole unit, 40 m thick, is regularly stratified in medium - to thin (3-25 cm) beds. The limestones and marly limestones prevail in the lower part. Local calcareous reworking materials are present. The unit can be partly or totally replaced by the Marna del Monte Serpone Fm. *Toarcian p.p.*

**Marna del M. Serpone**  
Green and grey marly limestones, in beds of various thickness, alternating with grey marls or shaly marls and grey-brown clastic limestones in medium-thick beds. The thickness varies from a few to 150 m. The age is variable and reaches up to *Hettangian p.p. - Toarcian p.p.*

**Comitola**  
Grey or brown limestones, in 10-50 cm thick beds (occasionally thicker), with nodules and ribbons of white and grey chert. Calcarenous turbidites and sometimes megabreccias and olistoliths of Calcare massiccio are frequently present, whereas grey-green thin shaly-marly interbeds are abundant in the upper part. The upper part can be replaced by the Marna del M. Serpone. The unit thickness can exceed 500 m. *Lower Sinemurian p.p. - Lower Toarcian p.p.*

## CONDENSED JURASSIC SUCCESSION

**Bugarone Group**  
Grey, brown or pink micrites, with nodular texture, locally dolomitized, in 20-40 cm thick beds, with green marls in the middle part, ammonites, crinoids particles and brachiopods are present. The thickness reaches 40 m. *Carixian p.p. - Lower Tithonian*

**Calcare massiccio**  
White, grey or pale brown limestones, made up of grainstone, packstones and less common wackestones. The unit is massive or coarsely bedded; the beds display cyclothem features, indicating a tidal environment. The uppermost part consists of bioclastic and ooid grainstone. The unit reaches a thickness of 700 m. *Hettangian - Carixian p.p.*
